NONOPERATIVE DILATATION OF CORONARY-ARTERY STENOSIS

Percutaneous Transluminal Coronary Angioplasty

ANDREAS R. GRÜNTZIG, M.D., ÅKE SENNING, M.D., AND WALTER E. SIEGENTHALER, M.D.

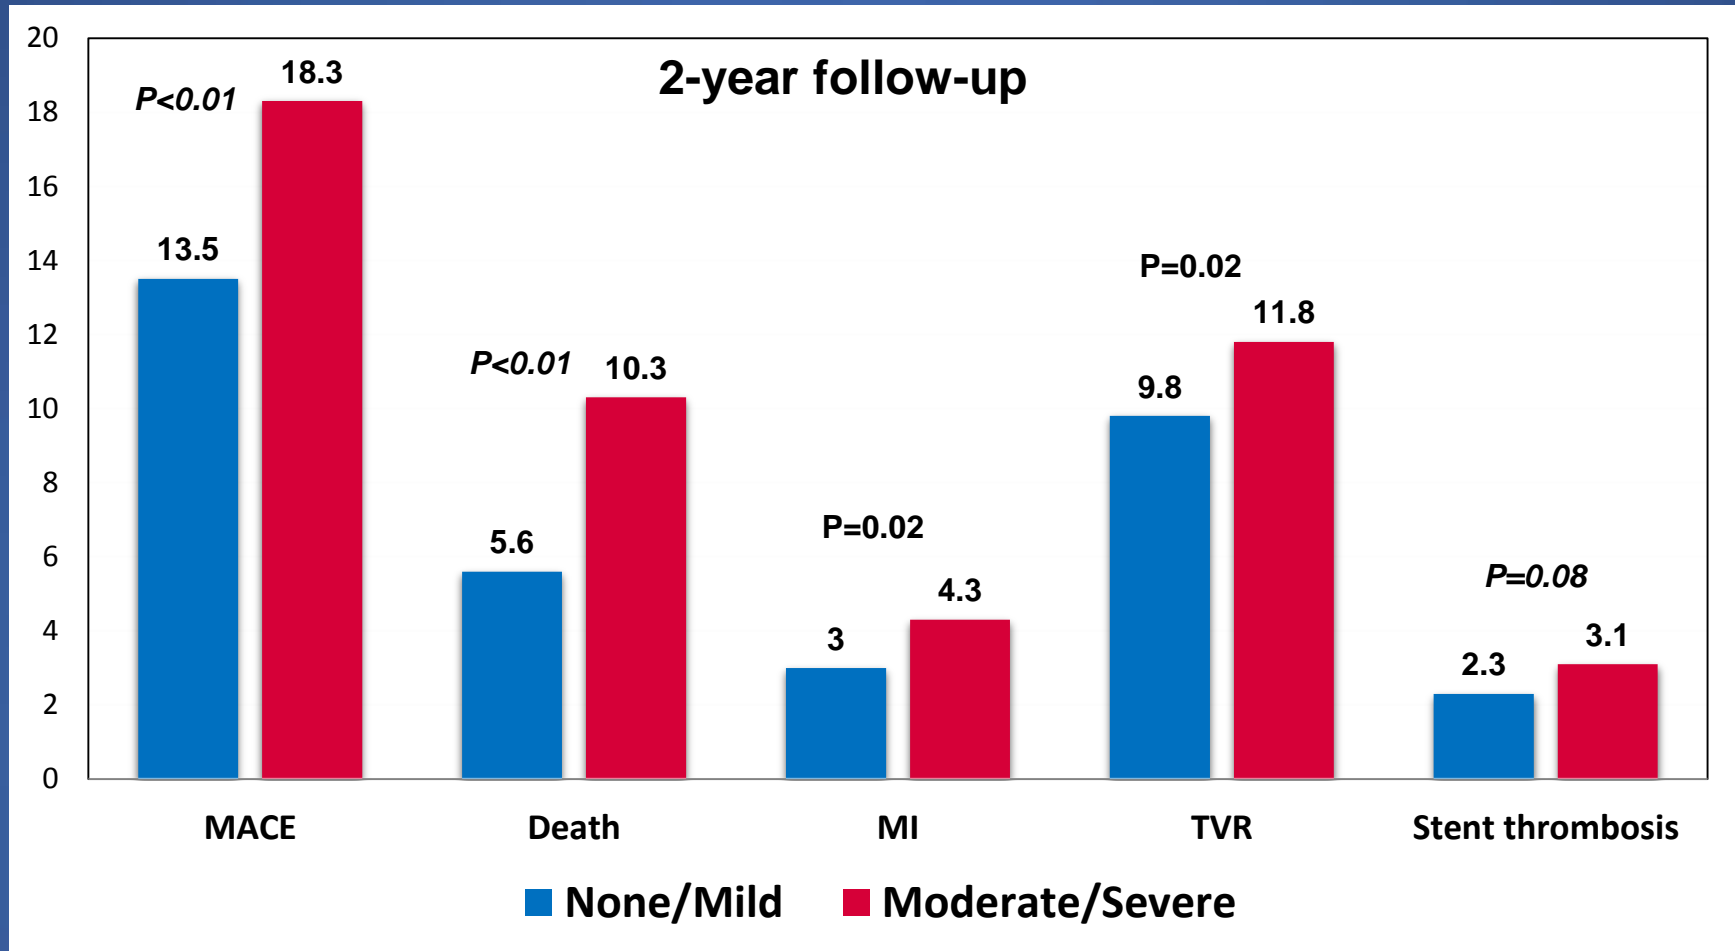

'At present, the [balloon-dilatation] technique is limited by anatomic factors, such as ... calcified stenoses.'¹

Challenges with Calcified Lesions

- **Difficult to treat**
 - Difficult to dilate
 - Prone to dissection during angioplasty
 - Difficulty delivering stent
 - Prevent adequate stent expansion
- **Poor clinical outcomes, including higher MACE**
 - Most trials excluded calcified lesions

Impact of Coronary Artery Calcification in PCI with PES *ARRIVE I and II Registries*

Rationale for Plaque Preparation with Coronary Atherectomy

- Improve procedural success
- Change morphology of lesion
- Facilitates optimal stent expansion
- Reduce complications

Orbital Atherectomy

Mechanism of Action

Differential Sanding:

- 30 micron diamond coating
- Bi-directional sanding, eccentric mounted crown
- Healthy elastic tissue flexes away minimizing damage to the vessel

Centrifugal Force:

- 360° crown contact designed to create a smooth, concentric lumen
- Allows constant blood flow and particulate flushing during orbit
- Increasing speed increases orbital diameter
- Ability to treat multiple vessel diameters with one crown (1.25 mm)
- Treat large vessels through small sheaths (6 French)

Single-Operator Technique

Objectives: We evaluated the safety and efficacy of orbital atherectomy in real-world patients with severe coronary artery calcification (CAC).

Background: The presence of severe CAC increases the complexity of percutaneous coronary intervention as it may impede stent delivery and optimal stent expansion. Atherectomy may be an indispensable tool for uncrossable or undilatable lesions by modifying severe CAC. Although the ORBIT I and II trials report that orbital atherectomy was safe and effective for the treatment of severe CAC, patients with kidney disease, recent myocardial infarction, long diffuse disease, severe left ventricular dysfunction, and unprotected left main disease were excluded.

Methods: This retrospective study included 458 consecutive patients with severe CAC who underwent orbital atherectomy followed by stenting from October 2013 to December 2015 at 3 centers.

Results: The primary endpoint of major adverse cardiac and cerebrovascular events at 30 days was 1.7%. Low rates of 30-day all-cause mortality (1.3%), myocardial infarction (1.1%), target vessel revascularization (0%), stroke (0.2%), and stent thrombosis (0.9%) were observed. Angiographic complications were low: perforation was 0.7%, dissection 0.9%, and no-reflow 0.7%. Emergency coronary artery bypass graft surgery was performed in 0.2% of patients.

Conclusion: In the largest real-world study of patients who underwent orbital atherectomy, including high-risk patients who were not surgical candidates as well as those with very complex coronary anatomy, acute and short-term adverse clinical event rates were low. A randomized clinical trial is needed to identify the ideal treatment strategy for patients with severe CAC. (J Intervent Cardiol 2016;9999:1–6)

	n=458
Perforation	3 (0.7%)
Dissection	4 (0.9%)
No reflow	3 (0.7%)

Orbital Atherectomy for Unprotected Left Main Disease

Calcified Left Main and LAD

68 y.o. male pre-lung transplant

Calcified LM and LAD

Orbital Atherectomy Left Main Artery

Derived, Filter: Filter 1

Treats 360° of the vessel. The diamond coated crown sands away calcium and allows healthy elastic tissue to flex away minimizing injury to the vessel.

Final Angiography

Conclusion

- Coronary artery calcification may prevent stent delivery and optimal stent expansion
- CAC is associated with increased risk of complications, including death, MI, TVR, and stent thrombosis
- Orbital atherectomy is a safe and effective treatment strategy for patients with severe CAC
- Low angiographic complications
- Acceptable rates of TVR
